Forklift Alternator

Forklift Alternators - A device utilized so as to change mechanical energy into electric energy is actually referred to as an alternator. It can perform this function in the form of an electric current. An AC electrical generator could basically also be called an alternator. However, the word is usually utilized to refer to a rotating, small machine driven by internal combustion engines. Alternators which are placed in power stations and are powered by steam turbines are referred to as turbo-alternators. Nearly all of these devices utilize a rotating magnetic field but from time to time linear alternators are likewise used.

A current is induced within the conductor if the magnetic field all-around the conductor changes. Generally the rotor, a rotating magnet, spins within a set of stationary conductors wound in coils. The coils are located on an iron core called the stator. If the field cuts across the conductors, an induced electromagnetic field otherwise called EMF is generated as the mechanical input makes the rotor to revolve. This rotating magnetic field generates an AC voltage in the stator windings. Typically, there are 3 sets of stator windings. These physically offset so that the rotating magnetic field produces 3 phase currents, displaced by one-third of a period with respect to each other.

In a "brushless" alternator, the rotor magnetic field could be caused by production of a permanent magnet or by a rotor winding energized with direct current through slip rings and brushes. Brushless AC generators are often found in bigger machines than those used in automotive applications. A rotor magnetic field could be generated by a stationary field winding with moving poles in the rotor. Automotive alternators usually use a rotor winding that allows control of the voltage generated by the alternator. It does this by varying the current in the rotor field winding. Permanent magnet machines avoid the loss due to the magnetizing current within the rotor. These devices are restricted in size due to the price of the magnet material. As the permanent magnet field is constant, the terminal voltage varies directly with the generator speed.
